ABSTRACT

TiC-TiB₂ composites (60/40 wt %) have been produced through self-propagating high-temperature synthesis (SHS), starting from low-cost raw materials like TiO₂, B₄C, and Mg. Using magnesium as a reductant allowed acid leaching of the undesired oxide product (MgO), leaving pure hard materials with fine particle size suitable to be employed in cutting tools manufacturing. The powders were characterized from a morphological and structural point of view. The leached powder were milled, cold pressed and sintered at suitable temperature. The densified samples were characterized by the point of view of cutting tools design.

Keywords: TiC-TiB₂ powders, SHS, sintering, cutting tools.
